

WEEK 4

The **Volume 20 SMA** measure was created using DAX. `DATESINPERIOD()` is used to calculate the average trading volume over the previous 20-day period.

The **Volume 50 SMA** measure was created using the same approach, with a 50-day period. This provides a longer-term moving average of trading volume.

The **MA Crossover Signal** measure was created to compare the 20-day and 50-day SMAs. It returns **“Bullish (20 > 50)”** when the 20-day SMA is higher and **“Bearish (20 < 50)”** otherwise.

The main **Close Price, Volume 20 SMA and Volume 50 SMA** line chart was created using the date field on the X-axis. The chart displays the stock price together with the two moving averages.

The chart configuration and visual filters were checked to ensure that **Close Price, Volume 20 SMA and Volume 50 SMA** were included correctly.

The **Zoom Slider** option was enabled from the visual formatting settings. This allows the user to zoom into specific portions of the stock price timeline.

A second chart was created to display **Trading Volume and Volume 20 SMA** over time. This helps compare actual trading activity with its moving average.

A **Volume Spike** DAX measure was created to identify dates where Trading Volume is greater than the 20-day SMA.

The **Volume Spike Highlight** measure was created to display the actual trading volume only when it exceeds the 20-day SMA. This makes high-volume periods easier to identify visually.

The **Volume Spike Highlight** measure was added to the volume chart along with Trading Volume and Volume 20 SMA, allowing volume spikes to stand out from the regular volume data.

A **Date Range Slicer** was added to the Power BI report using the Date Table[Date] field. The slicer was configured in **Between** mode, allowing the user to select a specific start and end date. This provides interactive control over the time period displayed in the stock price and trading volume visualizations.

A **Relative Date Slicer** was added using the Date Table[Date] field. The slicer was configured with the **Relative Date** style, allowing the stock data to be filtered dynamically based on a relative time period. This provides a convenient way to analyse recent periods without manually selecting specific start and end dates.

A **Field Parameter** named **Stock Price Metric** was created using Open Price, High Price, Low Price and Close Price. This allows different stock price measures to be selected dynamically.

The generated **Stock Price Metric** parameter was added to the model. The parameter contains Open Price, High Price, Low Price and Close Price as selectable options.

The main chart was updated with the **Stock Price Metric** parameter. The chart can now dynamically display different price measures while retaining the 20-day and 50-day moving averages.

A separate page named **Stock_Tooltip** was created for displaying additional stock information. The page was configured for use as a report tooltip.

A table was added to the tooltip page to display detailed stock values such as **Open Price, High Price, Low Price, Close Price and Trading Volume**.

The completed dashboard combines the **dynamic stock price chart, moving averages, trading volume visualization, date slicer and Stock Price Metric selector** into an interactive analysis page.

The final screenshot shows the **custom Stock_Tooltip appearing when hovering over the main chart**. It displays Open, High, Low, Close and Trading Volume values for the selected date, providing additional information without occupying space on the main dashboard.
